Abstract

The gastric ulcer is epidemic disease in many countries the main cause of the disease is *helicobacter pylori* which transfers by polluted foods. Many protocols and guidelines for the treatment and the most common guidelines is triple therapy Amoxicillin, Clarithromycin and proton pump inhibitors, but now the resistant to this protocol due to irrational use of the antibiotics. The study was done on the *Helicobacter pylori* by Kirby-Bauer sensitivity Test method which clarify that one of the components of the triple therapy clarithromycin, which failed to pass the test which indicates the retarding in the recovery to *H. Pylori* that open road to put new guidelines for *H. Pylori* especially in countries widely and irrationally use antibiotics. The study recommended that to put new guidelines and studies about the growing of resistant to antibiotics.

Keywords: *H. Pylori*; Protocol; Treatment; Antibiotic; Amoxicillin; Resistance; New Guidelines

Introduction

Background

Peptic ulcer disease (PUD) occurs when there is mucosal erosion within the gastrointestinal tract. The ulcer in PUD extend deeper into mucosa. The three-common cause of PUD are *H. pylori*, Non-steroidal anti-inflammatory drug (NSAIDs) induced ulcer and stress ulcer, which across in the presence of mechanically ventilated patient and critical illness [1].

Helicobacter pylori is found primarily in gastric antrum of the humane stomach, gram-negative microaerophilic and lived in acidic media. *H. pylori* represent (80-85%) of gastric ulcers. Pathophysiology associated with *H. pylori* involves the production of cytotoxins associated with gen A (CagA) proteins and vacuolating cytotoxin, such as vac A, which activate the inflammatory cascade. Cag A status are predictors of ulcerogenic capacity of strain. *H. pylori* produced number of enzymes causing tissue damage and include urease, hemolysis and neuraminidase. The main hormone involved in stimulating gastric acid secretion is gastrin. The hyperacidity in duodenal ulcer may result from hypergastrinemia caused by *H. pylori*. Consequence of bacterially mediated decrease of antral D cells that secrete somatostatin result from elevation of gastrin, those losing the inhibitory modulation of somatostatin on gastrin, or by the inflammatory process. The inflammatory process

is across by direct stimulation of gastrin cells. Increased partial cell mass cause long standing hypergastrinemia [1,2].

The symptoms and clinical manifestations

Peptic ulcer disease are dyspepsia, nausea, vomiting, anorexia, heartburn, cramping, bloating, abdominal pain is most frequent symptom of PUD burning and precipitate of ulcer pain with food [1].

The diagnosis

H. pylori infection by using endoscopic and non-endoscopic tests. The endoscopic test is costly, awkward and ordinarily require a mucosal biopsy for culture, histology, and location of urease movement while the non-endoscopic tests contain serologic counteracting agent location tests for identity circulating immunoglobulin G coordinated agonist *H. pylori*, the urea breath test utilized for location urease generation by *H. pylori*, and stool antigen test. The hemoglobin, hematocrit and stool hemocult tests are utilized to identify dying) [3].

Complication of peptic ulcer

The urea breath test utilized for location urease generation by *H. pylori*, and stool antigen test. The hemoglobin, hematocrit and stool hemocult tests are utilized to identify bleeding. Perforation

is happening as a sudden, sharp, starting to begin with within the epigastrium but quickly spread over the complete midriff and serious pain [3].

Epidemiology Saudi Arabia

Saudi Arabia is a developing country have good socioeconomic status. The prevalence rate in Saudi Arabia is 40% in age group of 5-10 years and 70% in people older than 20 years of age. *H. pylori* infection it's makes of highest endemic areas in world [4].

Goals of treatment

To healing the ulcer, relieving ulcer pain, preventing recurrence ulcer and redaction complication of ulcer. In patient have *H. pylori* positive an dynamic ulcer, a history of ulcer or an already recorded ulcer, the objective for this condition are destruction of living being case ulcer, mend the ulcer after killed life form and remedy malady agreeing taken a toll and compelling sedate regimen [3].

The treatment of *H. pylori*

According American guideline in Saudi Arabia by triple thereby and by fifth therapy (sequential). Triple thereby is amoxicillin, protein pump inhibitor (PPI) and Clarithromycin. And sequential is protein pump inhibitor (PPI) + amoxicillin (1g), protein pump inhibitor (PPI) + Clarithromycin (500 mg) + metronidazole (500 mg) [5]. In the other country like Asia in 2015 not have any alternative treatment to avoid resistance to antibiotics just increase dose of PPI [6]. And in the study doing in Iran levofloxacin is more preferred than clarithromycin if used in sequential therapy, vonoprazan is potassium-competitive acid blocker (P-CAB), vonoprazin orally available and cheaper than PPI and used in place of PPI in triple therapy in Japan [7]. But in Korea prevalence no resistance to metronidazole but increase prevalence of resistance with clarithromycin in dual therapy and need to antibiotics susceptibility test is necessary for prepatient [8]. In Bangladesh and in Africa therapy resistant to first line treatment of *H. pylori* the first line is metronidazole, amoxicillin and clarithromycin and have resistant to levofloxacin for patient in Bangladesh [9,10]. And in 2014 in Saudi Arabia the prevalence of resistant to antibiotics used in treatment of *H. pylori* is high for first line is 4% clarithromycin, 1% amoxicillin and metronidazole 80% and the alternative is tetracycline, amoxicillin and levofloxacin [4]. And in 2015 the effective of triple therapy and sequential thereby is similar in treatment of *H. pylori* and prevalence to resistance to clarithromycin 23.3%, amoxicillin 14.8% and 48.5% in metronidazole [11].

One of the reasons for the expanded resistance of *H. pylori* bacteria in Saudi Arabia is the irrational use of antibiotics. For example, amoxicillin is effective in America while it is resistant in Saudi Arabia as well as unlimited sales of antibiotics in Saudi Arabia and empirical treatment of the disease before sampling and testing Non-adherence to the specific treatment period for this drug occurs frequently in patients with stomach ulcers [12].

Antibiotics resistant mechanism for *H. pylori*

Bacteria are developing resistance to various antibiotics that Enables them to withstand the harsh environment and multiply. The

ways bacteria antimicrobial resistance is mutagenesis Disable the binding site of antibiotics, pump, and flow Horizontal gene transfer has been proposed. For example, resistance to Metronidazole mainly related to mutagenesis Inhibition of gene associated with reduction and oxidation (frxA and rdxA) [4].

The frxA gene may sometimes act indirectly by affecting cellularity. Low potential at low levels of metronidazole insulation resistance. Modifications in the rdxA gene such as deletion in the gene the pump flow system is also of great importance it was not possible to choose a clear board from this point mutations that can explain this phenomenon. In short, modification or loss of these genes may lead to metronidazole resistance. Quite the opposite. For clarithromycin, resistance the mechanism of convergence between ribosomes and clarithromycin is reduced. That's because the boom 23S rRNA gene in 2143 and 2144 function. In India, the result of a mutation in the nitrogen chromosome rdxA the gene, while in Bangladesh, is resistant to metronidazole inhibiting the rdxA gene to give the metronidazole phenotype. Saudi Arabia also suffers from pylori resistance [4].

The aim of this study is to set up a new standard and regimen within the treatment of stomach ulcers caused by *H. pylori* [4].

Microbiological Test

Microbiological test was done on isolated of *H. pylori* to study the effectiveness of antibiotics use in American guideline, also the test was done by other antibiotics to see their effect on this microorganism. Amoxicillin, Clarithromycin, and Amoxiclav acid Sensitivity Test using Disc diffusion Kirby-Bauer Sensitivity Test to study the effect of the antibiotics in the triple treatment of the Helicobacter Pylori and other antibiotics not present in the guideline.

Antibiotic disc preparation

- A. The filter paper was cut to a diameter of 4 mm and then placed in a sealed container and then sterilized the filter paper in the oven.
- B. The disks were impregnated with antibiotics (Amoxicillin and Clarithromycin and co-Amoxiclav) test suspensions in the oven at 60°C for minutes then serial dilution was carried out to obtain the concentration 10µg/ml as below equation: (Dissolve 1mg in 10ml and then the serial dilution was done according to the below equation):

$$Dilution\ factor = \frac{(r \times v)}{o}$$

Where:

- o: is the original concentration
- r: is the needed concentration
- v: is the needed volume

Inoculum was done from isolated bacteria under test.

H.pylori. Inocula are prepared by the direct inoculating colonies which grown overnight on Mueller Hinton agar, into the broth media. Then the *H. Pylori* tested was standardized by using McFarland turbidity test standard, Inoculums preparation is the most critical step in the any susceptibility test.

McFarland turbidity standards

The McFarland 0.5 standard is prepared and was used in this experiment, which consist of 99.5 ml of 1% sulfuric acid and 0.5 ml of 1.175% barium chloride, this solution is transferred into tubes comparable to those used for the inoculum's preparation.

The McFarland 0.5 standard gives the turbidity comparable to that turbidity of the bacterial suspension containing 1.5×10^8 CFU/ml.

Inoculation and incubation

After making the standard inoculums suspension, a sterile cotton swab was dipped into a turbid suspension, squeezed to remove the excess suspension, and then swabbed gently across surface of a agar plate (plates of 9mm are used) which Mueller Hinton agar was used. (Each the inoculum suspension was inoculated into two media labeled test (T) and control(C)).

- Within quarter an hour the inoculation, of the Amoxicillin, Clarithromycin, and Amoxiclav disks are applied to selected agar media with forceps and smoothly pressed to ensure contact with the surface of the agar.
- The Amoxicillin, Clarithromycin and amoxicillin/Clavulanic acid Test disks are applied in plates labeled (T)
- While another plate's labeled (c) without any antibiotic disks for control microbial growth.
- Within quarter an hour of the disk's placement, the plates are inverted and placed into oven at 37°C for 19 hours.
- After incubation, the plates were tested, to ensure test organisms have grown satisfactory, the diameter of each

inhibition zone was measured using ruler or calipers.

f) then zone of inhibition was measured in millimeters for each drug from Amoxicillin, Clarithromycin, and amoxicillin/Clavulanic acid compared with that found in the standard tables of the NCCLS documents (The national committee for clinical laboratory standards) [13].

Results and Discussion

The result of study shown that clear resistant to Clarithromycin and weak inhibition zone to Amoxicillin that result in agreement with Yoshio Yamaoka et al. [6] which summarize that In the other country like Asia in 2015 not have any alternative treatment to avoid resistance to antibiotics just increase dose of PPI [6]. same result by Anthony O'Connor et al. [7] which concluded that in study done in Iran levofloxacin is more preferred than clarithromycin if used in sequential therapy. Another finding by O'Connor that vonoprazan is potassium-competitive acid blocker (P-CAB), vonoprazan orally available and cheaper than PPI and used in place of PPI in triple therapy in Japan Eun CS et al. [8]. Another resemblance study by Eun et al. [8] in Korea that prevalence no resistance to metronidazole but increase prevalence of resistance with clarithromycin in dual therapy and need to antibiotics susceptibility test is necessary for prepatient Eun, et al. [8]. Those results in same matching with Hafeza A et al. [9] In Bangladesh and in Africa that the therapy resistant grown to treatment of *H. pylori* the first line is the metronidazole, amoxicillin and clarithromycin and have resistant to levofloxacin for patient in Bangladesh [9, 10]. Also in 2014 in Saudi Arabia the prevalence of resistant to antibiotics used in treatment of *H. pylori* is high for first line is 4% clarithromycin, 1% amoxicillin and metronidazole 80% and the alternative is tetracycline, amoxicillin and levofloxacin by Mohammed R et al. [4] which agree with finding of this study also another same results by Fahad A et al. [11] which reflect that the effective of triple therapy and sequential thereby is similar in treatment of *H. pylori* and prevalence to resistance to clarithromycin 23.3%, Amoxicillin 14.8% and 48.5% in metronidazole [11,14,15].

Figure 1: Inhibition Zone of Amoxicillin against *Helicobacter Pylori*.

Figure 2: Inhibition Zone of Clarithromycin against *Helicobacter Pylori* which clear the Resistant.

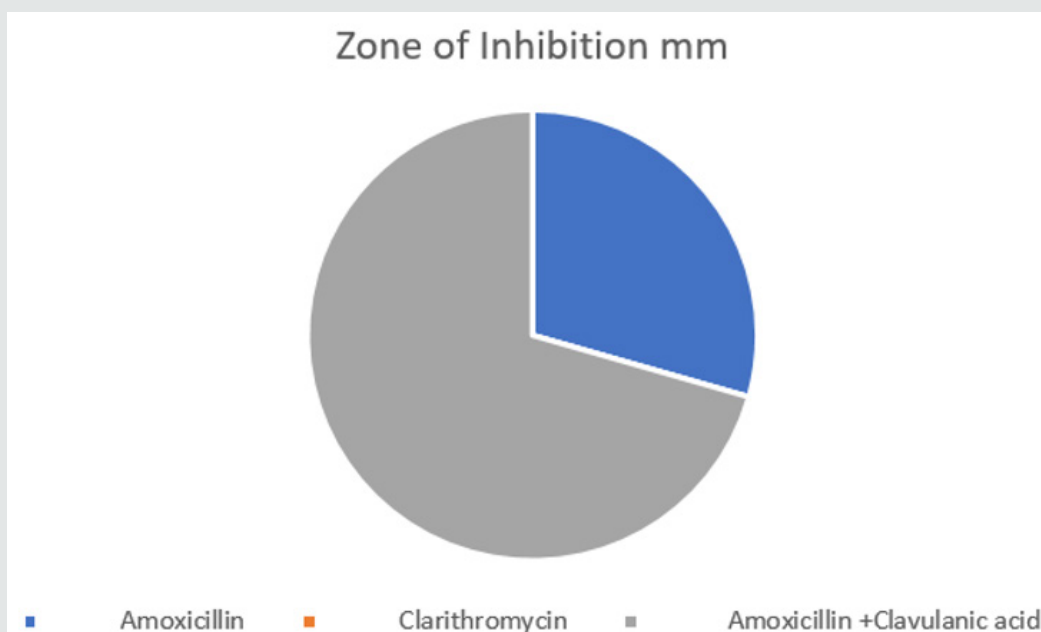

Figure 3: Percentage of resistant to antibiotics of triple therapy by *H. Pylori*.

Conclusion

The study found that high percentage of resistant to triple treatment protocol for *H. Pylori* due to might be for irrational use of antibiotics in Middle East countries and Africa compared to America and Europe.

Recommendations

This research recommend to distribute this study to make survey for the same drugs used in the triple treatment of *H. Pylori* and connected with this study furthermore to change the guidelines of triple treatment by using different antibiotics instead of macrolide with amoxicillin like Amoxicillin/Clavulanic acid for instance, due to the sensitivity to antibiotics in middle East countries and Africa not like America and Europe in restrictions laws for dispensing antibiotics.

The study invites all health practitioner to be restricted in dispensing the antibiotics and after ensure by making culture media.
