## Abstract

This short communication gives an overall account of small modular reactors and then walks through the nuclear micro reactors as the next generation of small modular reactors, which is the next wave of innovation for these SMRs. These next wave ride on the fact that future nuclear reactors are getting smaller and modular as well transportable. In this paper we are covering a summary and overall aspect of Generation IV (GEN-IV), or they are also known as Small Modular Reactors (SMRs) as well. In the book by Zohuri [1], we also, cover Nuclear Micro Reactor and its need and implementation within Department of Defense (DOD) military organizations.

**Keywords:** Small nuclear reactor; Nuclear reactor, Carbon monoxide; Transportable nuclear reactor; Combined cycle

## Introduction

Growth of population globally has direct impact on demand for energy. Almost 18% percent growth in population and their required daily life on energy and electricity demand presents a different dimension for production of electricity not only from renewable perspective, but also puts nuclear energy resource in different category. New generation of nuclear reactors in form of Small Modular Reactors (SMRs) or GEN-IV. With new safety factors built into these reactors, with better thermal out efficiency with innovative approach to Combined Cycle (CC) makes them more cost effective from Return On Investment (ROI) point of view[1-5]. Furthermore, the presence of new renewable technology and suggested solutions by expert in the field for source of energy and energy storage does not eliminate a demand and need for both present and near term Nuclear Fission Reactors in form of GEN-III (i.e., present) to GEN-IV (i.e., next generation of SMRs) to Nuclear Fusion Reactors in far term. The rule of thumb for generating of electricity is falling into the following category. The requirement for production of electricity is that the electricity generation rate at all times equal the demand for electricity. Economically achieving this goal is easy with fossil fuels because the primary cost of producing electricity is the cost of the fuel, not the cost of the power plant.

It is economically viable to operate a fossil plant at part load. As a consequence, in the United States and much of the world the preferred fossil fuel generating technology is the Gas Turbine Combined Cycle (GTCC)-a low cost machine with rapid response to variable electricity demand with heat-to-electricity efficiencies above 60%[1-2].

The major growth in the electricity production industry in the last 30 years has centered on the expansion of natural gas power plants based on gas turbine cycles. The most popular extension of the simple Brayton gas turbine has been the combined cycle power plant with the Air-Brayton cycle serving as the topping cycle and the Steam-Rankine cycle serving as the bottoming cycle for new generation of nuclear power plants that are known as GEN-IV. The Air-Brayton cycle is an open-air cycle, and the Steam-Rankine cycle is a closed cycle. The air-Brayton cycle for a natural gas driven power plant must be an open cycle, where the air is drawn in from the environment and exhausted with the products of combustion to the environment. This technique is suggested as an innovative approach to GEN-IV nuclear power plants in form and type of Small Modular Reactors (SMRs). The hot exhaust from the Air-Brayton cycle passes through a Heat Recovery Steam Generator (HSRG)

prior to exhausting to the environment in a combined cycle. The HRSG serves the same purpose as a boiler for the conventional Steam-Rankine cycle [5]. Given the climate change is real fact and low-carbon environment is a mandatory reality, a quest for a new source energy that provides electricity at zero carbon generation becomes a necessity. Thus, our choice of nuclear energy in form of either fission in near term or fusion in long term is there. In chapter 2 of the book by Zohuri [1] we discuss topic of "Why We Need Nuclear Power Plants" based on new innovative techniques to make them more efficient as well as safety point of view and cost effectiveness. Safety aspect of operational version of generation four (GEN-IV) of these reactors in form of SMRs are number one priority of owners of these reactors given the aftermath of events such as Fukushima Daiichi nuclear disaster (2011), the Chernobyl disaster (1986), the Three Mile Island accident (1979), and the SL-1 accident (1961) [5] are few we can name. The devastating impacts of climate change caused by burning fossil fuels are forcing countries around the world to look for zero-emissions alternatives for generating electricity.

One such alternative is nuclear energy as a clean source of energy that is free of carbon dioxide or monoxide generation, and the International Energy Agency (IEA) - a group focused on energy security, development, and environmental sustainability for 30-member countries - says the transition to a cleaner energy system will be drastically harder without it [6,7]. The next nuclear plants generation will be Small, Svelte and Safer. A new generation of reactors will start producing power in the next few years. They are comparatively tiny—and may be key to hitting our climate goals for better and free of carbon monoxide and dioxide and free of any greenhouse effects. For the last 20 years, the future of nuclear power has stood in a high bay laboratory tucked away on the Oregon State University campus in the western part of the state. Operated by NuScale Power in form of Small Modular Reactors, an Oregon-based energy startup, this prototype reactor represents a new chapter in the conflict-ridden, politically bedeviled saga of nuclear power plants. Or even old companies such as Westinghouse with many years of experience in nuclear power plant in form of Generation III and now with introduction of transportable Nuclear Micro Reactor eVinci, which has both space exploration into terrestrial domain and military application for a mobile brigade for a rapid deployment process.

NuScale's reactor will not need massive cooling towers or sprawling emergency zones. It can be built in a factory and shipped to any location, no matter how remote due to its modularization technical approach and it is built around old and traditional knowledge of Light Water Reactor technique. Extensive simulations suggest it can handle almost any emergency without a meltdown. One reason is that it barely uses any nuclear fuel, at least compared with existing reactors. It is also a fraction of the size of its predecessors. eVinci Micro Reactor cooling system is designed, and its cooling system is based on Advanced Heat Pipe technology which is a very dynamic yet as passive cooling system with most

safe way without any meltdown disasters either man made or natural threats. NASA's approach with heat pipe cooled of Kilopower reactor for space exploration and Mars's mission in near future is another application of these small reactors yet big energy source for such application that allows to travel beyond terrestrial space. This is good news for a planet in the grips of a climate crisis. Nuclear energy gets a bad rap in some environmentalist circles, but many energy experts and policymakers agree that splitting atoms is going to be an indispensable part of decarbonizing the world's electricity. In the US, nuclear power accounts for about two-thirds of all clean electricity, but the existing reactors are rapidly approaching the end of their regulatory lifetimes. Only two new reactors are under construction in the US, but they are billions of dollars over budget and years behind schedule.

Entering the Small Modular Reactor (SMR) technology approach is designed to allow several reactors to be combined into one unit and suggest the following advantages:

- a. Need a modest amount of energy.
- b. Install just a few modules.
- c. Want to fuel a sprawling city
- d. Tack on several more.

Coming up with a suitable power plant for a wide range of situations becomes that much easier. Because they are small, these reactors can be mass-produced and shipped to any location in a handful of pieces. Perhaps most importantly, small modular reactors can take advantage of several cooling and safety mechanisms unavailable to their big brothers, which all but guarantees they will not become the next Chernobyl or Fukushima. Nuclear is getting smaller... and it is opening up some big opportunities for the industry. A handful of microreactor designs are under development in the United States and they could be ready to roll out within the next decade. These plug-and-play reactors will be small enough to transport by truck and could help solve energy challenges in a number of areas, ranging from remote commercial or residential locations to military bases.

The devastating impacts of climate change caused by burning fossil fuels are forcing countries around the world to look for zero-emissions alternatives for generating electricity. One such alternative is nuclear energy, and the International Energy Agency — a group focused on energy security, development, and environmental sustainability for 30-member countries — says the transition to a cleaner energy system will be drastically harder without it. Canada's government appears to be on board, saying nuclear innovation plays a "critical role" in reducing greenhouse gas emissions as Canada moves toward a low-carbon future.

While husky CANDU reactors a Canadian design nuclear fission reactor, have powered some Canadian communities for decades, governments are now eyeing technology of a different scale. The federal government describes small modular reactors (SMR), as

the “next wave of innovation” in nuclear energy technology and an “important technology opportunity for Canada”.

- I. Here is what you need to know about them.
- II. What is a small modular reactor?

Traditional nuclear reactors used in Canada can typically generate about 800 megawatts of electricity, or about enough to power about 600,000 homes at once (assuming that 1 megawatt can power about 750 homes). The International Atomic Energy Agency (IAEA), the United Nation (UN) organization for nuclear co-operation, considers a nuclear reactor to be “small” if it generates under 300 megawatts.

### Nuclear Micro Reactor Generation

A new generation of reactors will start producing power in the next few years. They are comparatively tiny—and may be key to hitting our climate goals for the better, free of carbon emissions and free from greenhouse effects. For the last 20 years, the future of nuclear power has stood in a high bay laboratory tucked away on the Oregon State University campus in the western part of the state. Operated by NuScale Power in the form of Small Modular Reactors (SMR), an Oregon-based energy startup, this prototype reactor represents a new chapter in the conflict-ridden, politically bedeviled saga of nuclear power plants. Or even old companies such as Westinghouse with many years of experience in nuclear power plant in the form of Generation III and now with introduction of transportable Nuclear Micro Reactor eVinci, which has both space exploration into terrestrial domain and military application for a mobile brigade for a rapid deployment process.

NuScale’s reactor will not need massive cooling towers or sprawling emergency zones. It can be built in a factory and shipped to any location, no matter how remote due to its modulization technical approach, and it is built around old and traditional knowledge of Light Water Reactor technique. Extensive simulations suggest that it can handle almost any emergency without a meltdown. One reason for that is it barely uses any nuclear fuel—at least compared with existing reactors. eVinci Micro Reactor cooling system is designed, and its cooling system is based on Advanced Heat Pipe technology which is a very dynamic yet as passive cooling system with most safe way without any meltdown disasters either manmade or natural threats.

NASA’s approach with heat pipe cooled of kilo-power reactor for space exploration and Mars’s mission in near future is another application of these small reactors yet big energy source for such application that allows to travel beyond terrestrial space. This is good news for a planet in the grips of a climate crisis. Nuclear energy gets a bad rap in some environmentalist circles, but many energy experts and policymakers agree that splitting atoms is going to be an indispensable part of decarbonizing the world’s electricity. In the United States, nuclear power accounts for about two-thirds of all clean electricity, but the existing reactors are rapidly approaching the end of their regulatory lifetimes. Only two new

reactors are under construction in the United States, but they are billions of dollars over budget and years behind schedule.

### Nuclear Micro Reactor Research, Development, and Deployment

The US Department of Energy (DOE) has opened the National Reactor Innovation Centre (NRIC) to support the development of advanced nuclear energy technology. A result of the Nuclear Energy Innovation Capabilities Act (NEICA), the new center is located at the Idaho National Laboratory (INL) in Idaho Falls, USA. The act was signed into law in 2018 to accelerate the development of advanced reactors in the country by eliminating financial and technical barriers. The US energy secretary said: “NRIC will enable the demonstration and deployment of advanced reactors that will define the future of nuclear energy.” He also stated, “By bringing the industry together with our national labs and university partners, we can enhance our energy independence and position the US as a global leader in advanced nuclear innovation.” Technology developers from the private industry will receive support from NRIC required to test, demonstrate, and evaluate the performance of their reactor concepts.

It will also help technology developers in speeding-up the licensing and commercialization of their new nuclear energy systems. As per Idaho Senator Mike Crapo, “This is the ultimate public-private sector partnership that will take the next step to grow clean nuclear power across the nation.” It makes sense that the INL is the place where private developers will now work with the Department of Defense and Nasa to come and demonstrate new nuclear technologies. I look forward to seeing micro reactors and small modular reactors being built here. The best is yet to come!”. NRIC aims to demonstrate small modular reactor and micro reactor concepts in the next 5 years. In the fiscal year 2020 budget, the House Energy and Water Development committee had set aside \$5 million for NRIC [8].

### Conclusion

We a need for new source of energy both renewable and non-renewable to produce electricity and meet the need by demand, we have no choice except accept nuclear energy as an unlimited source of energy, going forward with our modern technological life around us. With growth of population and their need for more and more electrical and electronical gadget on daily basis, our demand for electricity is on rise with a sharp ascending slop.

Production of electricity based on rising demand cannot just be relying on renewable energy such as Solar, Wind, Hydro, or other natural source of energy alone. With a barrier to nuclear, while safety remains a paramount concern for such source of energy, many in the industry say they no longer view public perception as a major problem. Advanced reactors are not just a garden science experiment, “said Murkowski”. There is a real private sector interest. There is capital being invested to make [them] a reality, “but developing a first of its kind technology, we all know, is not

for the risk averse, it's not for the faint of heart". With large capital investments, such as nuclear, some of that risk can turn away private investment, said Colbert. "If you look at nuclear, the market for energy ... is pretty well known," he said. "What's not so well known is how do you get through the nuclear regulatory process, the [Nuclear Regulatory Commission] process".
