Introduction

Psychological stress is a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression. It greatly affects both older and younger ages globally. Thus, searching for new non-drug training strategies for ameliorating psychological stress are recommended.

Background: Psychological stress is a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression. It greatly affects both older and younger ages globally. Thus, searching for new non-drug training strategies for ameliorating psychological stress are recommended.

Aim: The aim of the present study was to characterize the rate of psychological stress among students of faculty of sports sciences and to evaluate the efficacy of a particular relaxing gradual technique called progressive muscle relaxing (PMR) for ameliorating the mood and for returning the psychological stress parameters into normal levels.

Methods: Psychological stress was evaluated in 40 of students of faculty of sports sciences aged 18-21 years old. They are classified into two groups according to the scores of psychological stress; control group (n=20) and Psychological stress group (n=20). For the treatment of psychological stress, both groups participated in PMR- training intervention (2 times /week) for 12 weeks.

Results: In this study, psychological stress parameters were significantly reported in 50% (20/40) of the participated students. PMR- training interventions showed a gradual significant reduction in total psychological stress scores and other related parameters; family stress, study stress, economic stress, and social stress respectively. These results greatly support the use of PMR gradual interventions for the reduction of psychological stress among younger ages.

Conclusion: Application of PMR training interventions for 12 weeks gradually and significantly improve psychological stress among the students of faculty of sports sciences. It could be supported as non-drug training treatment among psychological stress holders, particularly in younger ages.

Keywords: Gradual Muscular Relaxation; Sports Psychology; Psychological Stress
the individuals experience many emotional, behavioral, sexual, economic, academic and social conflicts which result in social and physical changes [6-7].

Thus, in this period the emotional health of university youth becomes one of the important components of social health [6-8]. For this reason, it is important to detect the status of psychological stress among younger ages and to find good solutions to overcome these contradictions.

Progressive muscle relaxation (PMR) is a technique for reducing stress and anxiety by alternately tensing and relaxing the muscles as previously reported [9-11]. It mainly requires both a physical and a mental component. Previous research reports recommended several benefits of PMR technique including a reduction in salivary cortisol levels and generalized anxiety [10] decreased blood pressure and heart rate [10,12], decreased headaches [13], better management of cardiac rehabilitation [14] improvement of quality of life of patients with chronic diseases or following severe surgical operations [15-16]. Thus it is better to use PMR technique in for ameliorating psychological stress among younger ages. Thus, it is important to identify the psychological stress among younger ages and find out an alternative non-drug remedy to overcome this stress. In this regard, the aim of the present study was to characterize the rate of psychological stress among students of faculty of sports sciences and to evaluate the efficacy of a particular relaxing gradual technique called progressive muscle relaxing (PMR) for ameliorating the mood and for returning the psychological stress parameters into normal levels.

Materials and Methods

Participants

A total of 40 of Students of Faculty of Sport Sciences aged 18-21 years old from College of Sport Sciences & Physical Activity, King Saud University, Riyadh, Saudi Arabia. were enrolled in this study. Students who had serious acute or chronic health problems such as diabetes, endocrine disorders, cardiovascular disease, systemic infections, musculoskeletal disorders, or concentration problems or as previously reported [9,10]. In this techniques all students performed the PMR training interventions 2 times /week for 12 weeks. In this training program, the physical component involves tensing and relaxing of muscle groups over the legs, abdomen, chest, arms, and face. In a sequential pattern, with eyes closed, the tension of the individual place in a given muscle group purposefully for approximately 10 seconds and then releases it for 20 seconds before continuing with the next muscle group [9-11]. The mental component requires that the individual focuses on the distinction between the feelings of tension and relaxation. Relaxation must be attempted in order to reduce pain or pain perception and tension, create a pleasant mental state, enhance the performance of physical activities and help in the relationship with others [11-12].

Statistical Analysis

An SPSS software (Statistical Package for the Social Sciences, version 18.0, SPSS Inc. Chicago, IL, USA) was used to perform statistical analyses. The qualitative variables were presented in terms of frequencies and percentage, and the quantitative variables were presented using mean and standard deviation. For analyses within the groups, we used a t-test for paired data. The unpaired t-test was used for within and between groups. The comparison and correlation of the studied parameters were investigated using both Student’s t-test and Pearson’s correlation coefficient, respectively Values at p<0.05 were considered statistically significant.

Results

In this study, all psychological stress parameters; family stress, study stress, economic stress, and social stress, and the effect of progressive muscle training interventions on the degree of psychological stress were characterized in 40 healthy university students. Based on the degree of the severity of psychological stress scores, the participants classified into two groups; control healthy (n=20) and psychological stress (n=20) as shown in (Table 1). There is no significant difference in age, BMI, but WHR of adiposity showed little non-significant change in psychological students compared with healthy controls (Table 1). The results showed that students with higher scores of psychological stress parameters require more non-drug support interventions.

In this current study, both control and psychological students participated in PMR training interventions for 12 weeks (2 times /week) and the effect of PMR –exercise on psychological stress was evaluated as shown in (Table 2) and (Figure 1). PMR-Post results showed that all psychological parameters were significantly declined and improved in all healthy (P=0.01) and students with psychological stress (P=0.001) as shown in (Table 2). The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment as shown in (Figure 1).

Discussion

In this study, psychological stress parameters were significantly reported in 50% (20/40) of the participated students. These results greatly require to find out more non-drug supportive interventions for the reduction of the psychological stress among younger ages. The data matched with those who reported significant collateral damage associated with severe diseases among both older and younger ages [1,2]. A harmful consequence was reported among youth and young students [3-5], in which disturbances were reported in all psychological, physiological and behavioral proceed [2]. In addition, psychological stress was reported as a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression [1]. These consequences in turn greatly affects in many emotional, behavioral, sexual, economic, academic and social conflicts of young ages and result in social and physical changes [6,7]. Recently, the importance of psychological skills training (PST) techniques and other relating training techniques have been recognized, and the number of studies on athletes or other patient subjects using psychological training strategies to improve psychological status [19-21]. One of the most training techniques affecting on psychological stress is Progressive muscle relaxation (PMR) [9-11]. It showed to reduce a stress and anxiety by alternately tensing and relaxing the muscles as previously reported [9-11]. It mainly requires both a physical and a mental component of the subject during treatment sessions. In this current study, both control and psychological students participated in PMR training interventions for 12 weeks (2 times/week). PMR-Post results showed that all psychological parameters were significantly declined and improved in all healthy (P=0.01) and students with psychological stress (P=0.001). The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment which support its efficacy as a non-drug strategy for treating psychological stress and its consequences among younger ages.

Previous research reports recommended several benefits of PMR technique including a reduction in salivary cortisol levels and generalized anxiety [10], decreased blood pressure and heart rate [10,12], decreased headaches [13], better management of cardiac rehabilitation [14] improvement of quality of life of patients with chronic diseases or following severe surgical operations [15-16]. Thus it is better to use PMR technique in for ameliorating psychological stress among younger ages. Previous treatment strategies with predominant skeletal muscle components asfoten to produce greater muscular effects particularly; a decrease in muscle tone and tension. Different versions including, PMR, biofeedback, yoga, and systematic breathing are the most investigated techniques in this domain [22]. Progressive muscle relaxation and its derivations have received the most attention in scientific context whereas it significantly deliberate and continuously reduce of tension in specific muscle groups of the locomotor system [9]. A review on the use of PMR in clinical trials revealed moderate to large effect sizes on the effectiveness of PMR [23,24].

Conclusion

In this study, PMR training interventions for 12 weeks significantly improve psychological stress among the students of faculty of sports sciences. The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment which supports the use of this non-drug treatment among psychological stress holders, particularly in younger ages.
